What's wrong with MapReduce?

从MapReduce说起

- 最大缺陷：网络、磁盘I/O

怎么办？

- 放内存：分布式内存计算

MapReduce其他不足：

- 抽象层次低，需要手工代码
- 只提供Map和Reduce，表达力欠缺
- 复杂的计算需要大量的Job完成，Job之间的依赖关系是由开发者自己管理的
- 处理逻辑隐藏在代码细节中，没有整体逻辑
- ReduceTask需要等待所有MapTask都完成后才可以开始；
- 时延高，只适用Batch数据处理，不适合交互式数据、实时数据，迭代式数据处理性能比较差。

Frameworks after Hadoop (before Spark): Twister

- Twister: Iterative MapReduce
(<http://www.iterativemapreduce.org>). Twister is a lightweight MapReduce runtime we have developed by incorporating these enhancements. (initially developed by Indiana University)
 - Distinction on static and variable data
 - Configurable long running (cacheable) map/reduce tasks
 - Pub/sub messaging based communication/data transfers
 - Efficient support for Iterative MapReduce computations (extremely faster than Hadoop or Dryad/DryadLINQ)
 - Combine phase to collect all reduce outputs
 - Data access via local disks
 - *Lightweight* (~5600 lines of Java code)
 - Support for typical MapReduce computations Tools to manage data

Twister: Overview

Iterative MapReduce programming model using Twister

Frameworks after Hadoop (before Spark): HaLoop

HaLoop: modified version of the open source MapReduce implementation Hadoop

(<https://homes.cs.washington.edu/~magda/papers/bu-vldb10.pdf>)

- Providing a new application programming interface to simplify the iterative expressions.
- An automatic generation of Map reduce program by the master node using a loop control module until the loop condition is met.
- The new task scheduler supports data locality in these application in order to efficiently perform iterative operations.
- The task scheduler and task tracker are modified not only to manage execution but also manage cache indices on slave module.

HaLoop: overview

Who's using Spark?

Spark经典案例

- 腾讯 – 广点通pCTR投放系统。基于日志的快速查询系统构建于Spark之上的Shark，比Hive快2-100倍
- Yahoo – 定向广告业务。基于广告者提供的观看广告并购买产品的样本客户，学习并寻找更多可能转化的用户
- 淘宝 – 阿里搜索和广告业务。从Mahout或自己写的MR解决复杂机器学习到使用Spark、Graphx运用于相关推荐算法
- 优酷土豆 – 视频推荐(图计算)、广告业务等。Spark相比于Hadoop交互查询响应快；模拟广告投放计算效率高、延迟小；机器学习、图计算等迭代计算，大大减少了网络传输、数据落地等

Spark Stack

Spark Core

Basic functionality of Spark, including components for:

- Task Scheduling
- Memory Management
- Fault Recovery
- Interacting with Storage Systems
- and more

Home to the API that defines resilient distributed datasets (RDDs) - Spark's main programming abstraction.

RDD represents a collection of items distributed across many compute nodes that can be manipulated in parallel.

Download Apache Spark™

1. Choose a Spark release: 
2. Choose a package type: 
3. Download Spark: [spark-2.3.0-bin-hadoop2.7.tgz](#)
4. Verify this release using the [2.3.0 signatures and checksums](#) and [project release KEYS](#).

Note: Starting version 2.0, Spark is built with Scala 2.11 by default. Scala 2.10 users should download the Spark source package and build with Scala 2.10 support.

Link with Spark

Spark artifacts are [hosted in Maven Central](#). You can add a Maven dependency with the following coordinates:

```
groupId: org.apache.spark  
artifactId: spark-core_2.11  
version: 2.3.0
```

First language to use — Python

The screenshot shows the Python.org homepage. At the top, there's a navigation bar with links for About, Downloads, Documentation, Community, Success Stories, News, and Events. A search bar and social sharing buttons are also present. Below the navigation, a code snippet in the Python interpreter is displayed:

```
# Python 3: Use comprehension to n
>>> fruits=['Banana', 'Apple', 'Lime']
>>> [fruit[0].upper() for fruit in
#fruits] while a < b:
>>> print(tuple(fruit[0] for fruit
(['BANANA', 'APPLE', 'LIME']
>>> print()
>>> list and the enumerate function
0 1 2 3 5 8 13 21 34 55 89 144 233 377 610
@0, 'Banana'), (1, 'Apple'), (2, 'Lime'))
```

To the right of the code, there's a section titled "Compound Data Types" with a brief description and a link to "More about lists in Python 3". Below the code, there are five numbered buttons (1, 2, 3, 4, 5). At the bottom of the page, a promotional message reads: "Python is a programming language that lets you work quickly and integrate systems more effectively. [» Learn More](#)".

Disable logging

You may find the logging statements that get printed in the shell distracting. You can control the verbosity of the logging. To do this, you can create a file in the `conf` directory called `log4j.properties`. The Spark developers already include a template for this file called `log4j.properties.template`. To make the logging less verbose, make a copy of `conf/log4j.properties.template` called `conf/log4j.properties` and find the following line:

```
log4j.rootCategory=INFO, console
```

Then lower the log level so that we show only the WARN messages, and above by changing it to the following:

```
log4j.rootCategory=WARN, console
```

Core Spark Concepts

- At a high level, every Spark application consists of a **driver program** that launches various parallel operations on a cluster.
- The driver program contains your application's main function and defines distributed databases on the cluster, then applies operations to them.
- In the preceding example, the driver program was the Spark shell itself.
- Driver programs access Spark through a `SparkContext` object, which represents a connection to a computing cluster.
- In the shell, a `SparkContext` is automatically created as the variable called `sc`.

Driver Programs

Driver programs typically manage a number of nodes called **executors**.

If we run the count() operation on a cluster, different machines might count lines in different ranges of the file.

Example filtering

```
>>> lines = sc.textFile("README.md")  
  
>>> pythonLines = lines.filter(lambda line: "Python" in line)  
  
>>> pythonLines.first()  
u'## Interactive Python Shell'
```

lambda —> define functions inline in Python.

```
def hasPython(line):  
    return "Python" in line  
  
pythonLines = lines.filter(hasPython)
```

Running as a Standalone Application

In Python, you simply write applications as Python scripts, but you must run them using the `bin/spark-submit` script included in Spark. The `spark-submit` script includes the Spark dependencies for us in Python. This script sets up the environment for Spark's Python API to function. Simply run your script with the line given in [Example 2-6](#).

Example 2-6. Running a Python script

```
bin/spark-submit my_script.py
```

Example — word count

```
import sys
from operator import add

from pyspark import SparkContext

if __name__ == "__main__":
    if len(sys.argv) != 2:
        print >> sys.stderr, "Usage: wordcount <file>"
        exit(-1)
    sc = SparkContext(appName="PythonWordCount")
    lines = sc.textFile(sys.argv[1], 1)
    counts = lines.flatMap(lambda x: x.split(' '))
                      .map(lambda x: (x, 1))
                      .reduceByKey(add)
    output = counts.collect()
    for (word, count) in output:
        print "%s: %i" % (word, count)

    sc.stop()
```

Resilient Distributed Dataset (RDD) Basics

- An RDD in Spark is an immutable distributed collection of objects.
- Each RDD is split into multiple partitions, which may be computed on different nodes of the cluster.
- Users create RDDs in two ways: by loading an external dataset, or by distributing a collection of objects in their driver program.
- Once created, RDDs offer two types of operations: **transformations** and **actions**.

```
>>> lines = sc.textFile("README.md")           <== create RDD  
  
>>> pythonLines = lines.filter(lambda line: "Python" in line)    <== transformation  
  
>>> pythonLines.first()                  <== action  
u'## Interactive Python Shell'
```

Transformations and actions are different because of the way Spark computes RDDs.
=> Only computes when something is, the first time, in an action.

[What] 什么是Resilient Distributed Datasets (RDD) ?

- 不变的、容错的、并行的数据结构
- 显式地将数据存储到磁盘和内存中，并能控制数据的分区

[Why] 为什么要RDD ?

- 数据处理常见模型：1. Iterative Algorithms (迭代算法) ; 2.Relational Queries (关联查询) ; 3.MapReduce; 4. Stream Processing (流式处理)
- RDD支持四种模型

[How] 如何构建RDD ?

- 从文件系统
- 通过Scala集合对象并行化生成
- 通过对已存在的RDD transform生成
- 通过改变其他RDD的持久化状态

RDD Transformations和Actions

核心API：

- Map : 集合元素A=>B, 可以**变化类型**
- Reduce/ReduceByKey : **归约计算**, 得到RDD(K,V)
- Filter : 元素**个数可能减少**, 类型不变
- Flattern : 把**嵌套的集合做成非嵌套**

What's that?

MAP运算

map

FOLD/REDUCE运算

fold

```
scala> List(1,2,3).foldLeft(0)(_ + _)  
res8: Int = 6
```

```
scala> List(1,2,3).foldLeft(List[Int]())((acc,i) => i :: acc)  
res8: List[Int] = List(3, 2, 1)
```

```
scala> List(1,2,3).reduce(_ * _)  
res11: Int = 6
```

ReduceByKey

FILTER运算

filter ??? ==

```
scala> List(1,2,2).filter(_ == 2)  
res2: List[Int] = List(2, 2)
```

ReduceByKey

FLATTEN运算

```

scala> List(List(1,2),Nil,List(3)).flatten
res10: List[Int] = List(1, 2, 3)

```

RDD transformations and actions

RDD Transformations和Actions

Transformations	$\text{map}(f : T \Rightarrow U) : \text{RDD}[T] \Rightarrow \text{RDD}[U]$ $\text{filter}(f : T \Rightarrow \text{Bool}) : \text{RDD}[T] \Rightarrow \text{RDD}[T]$ $\text{flatMap}(f : T \Rightarrow \text{Seq}[U]) : \text{RDD}[T] \Rightarrow \text{RDD}[U]$ $\text{sample}(\text{fraction} : \text{Float}) : \text{RDD}[T] \Rightarrow \text{RDD}[T] \text{ (Deterministic sampling)}$ $\text{groupByKey}() : \text{RDD}[(K, V)] \Rightarrow \text{RDD}[(K, \text{Seq}[V])]$ $\text{reduceByKey}(f : (V, V) \Rightarrow V) : \text{RDD}[(K, V)] \Rightarrow \text{RDD}[(K, V)]$ $\text{union}() : (\text{RDD}[T], \text{RDD}[T]) \Rightarrow \text{RDD}[T]$ $\text{join}() : (\text{RDD}[(K, V)], \text{RDD}[(K, W)]) \Rightarrow \text{RDD}[(K, (V, W))]$ $\text{cogroup}() : (\text{RDD}[(K, V)], \text{RDD}[(K, W)]) \Rightarrow \text{RDD}[(K, (\text{Seq}[V], \text{Seq}[W]))]$ $\text{crossProduct}() : (\text{RDD}[T], \text{RDD}[U]) \Rightarrow \text{RDD}[(T, U)]$ $\text{mapValues}(f : V \Rightarrow W) : \text{RDD}[(K, V)] \Rightarrow \text{RDD}[(K, W)] \text{ (Preserves partitioning)}$ $\text{sort}(c : \text{Comparator}[K]) : \text{RDD}[(K, V)] \Rightarrow \text{RDD}[(K, V)]$ $\text{partitionBy}(p : \text{Partitioner}[K]) : \text{RDD}[(K, V)] \Rightarrow \text{RDD}[(K, V)]$
Actions	$\text{count}() : \text{RDD}[T] \Rightarrow \text{Long}$ $\text{collect}() : \text{RDD}[T] \Rightarrow \text{Seq}[T]$ $\text{reduce}(f : (T, T) \Rightarrow T) : \text{RDD}[T] \Rightarrow T$ $\text{lookup}(k : K) : \text{RDD}[(K, V)] \Rightarrow \text{Seq}[V] \text{ (On hash/range partitioned RDDs)}$ $\text{save}(path : \text{String}) : \text{Outputs RDD to a storage system, e.g., HDFS}$

Persistance in Spark

- By default, RDDs are computed each time you run an action on them.
- If you like to reuse an RDD in multiple actions, you can ask Spark to persist it using `RDD.persist()`.
- `RDD.persist()` will then store the RDD contents in memory and reuse them in future actions.
- Persisting RDDs on disk instead of memory is also possible.
- The behavior of not persisting by default seems to be unusual, but it makes sense for big data.

Example 3-4. Persisting an RDD in memory

```
>>> pythonLines.persist  
>>> pythonLines.count()  
2  
  
>>> pythonLines.first()  
u'## Interactive Python Shell'
```

To summarize, every Spark program and shell session will work as follows:

1. Create some input RDDs from external data.
2. Transform them to define new RDDs using transformations like `filter()`.
3. Ask Spark to `persist()` any intermediate RDDs that will need to be reused.
4. Launch actions such as `count()` and `first()` to kick off a parallel computation, which is then optimized and executed by Spark.

Parallelizing in Spark

The simplest way to create RDDs is to take an existing collection in your program and pass it to `SparkContext's parallelize()` method. But, that needs all dataset in memory on one machine.

Example 3-5. `parallelize()` method in Python

```
lines = sc.parallelize(["pandas", "i like pandas"])
```

Spark file loading

Table 5-1. Common supported file formats

Format name	Structured	Comments
Text files	No	Plain old text files. Records are assumed to be one per line.
JSON	Semi	Common text-based format, semistructured; most libraries require one record per line.
CSV	Yes	Very common text-based format, often used with spreadsheet applications.
SequenceFiles	Yes	A common Hadoop file format used for key/value data.
Protocol buffers	Yes	A fast, space-efficient multilanguage format.
Object files	Yes	Useful for saving data from a Spark job to be consumed by shared code. Breaks if you change your classes, as it relies on Java Serialization.

Loading and Saving

Example 5-1. Loading a text file in Python

```
input = sc.textFile("file:///home/holden/repos/spark/README.md")
```

Example 5-5. Saving as a text file in Python

```
result.saveAsTextFile(outputFile)
```

Example 5-6. Loading unstructured JSON in Python

```
import json
data = input.map(lambda x: json.loads(x))
```

Example 5-9. Saving JSON in Python

```
(data.filter(lambda x: x['lovesPandas']).map(lambda x: json.dumps(x))
 .saveAsTextFile(outputFile))
```

Loading and Saving (II)

Example 5-12. Loading CSV with textFile() in Python

```
import csv
import StringIO
...
def loadRecord(line):
    """Parse a CSV line"""
    input = StringIO.StringIO(line)
    reader = csv.DictReader(input, fieldnames=["name", "favouriteAnimal"])
    return reader.next()
input = sc.textFile(inputFile).map(loadRecord)
```

Example 5-18. Writing CSV in Python

```
def writeRecords(records):
    """Write out CSV lines"""
    output = StringIO.StringIO()
    writer = csv.DictWriter(output, fieldnames=["name", "favoriteAnimal"])
    for record in records:
        writer.writerow(record)
    return [output.getvalue()]

pandaLovers.mapPartitions(writeRecords).saveAsTextFile(outputFile)
```

Loading and Saving (III)

Example 5-20. Loading a SequenceFile in Python

```
val data = sc.sequenceFile(inFile,
    "org.apache.hadoop.io.Text", "org.apache.hadoop.io.IntWritable")
```

File compression options

Table 5-3. Compression options

Format	Splittable	Average compression speed	Effectiveness on text	Hadoop compression codec	Pure Java	Native	Comments
gzip	N	Fast	High	org.apache.hadoop.io.compress.GzipCodec	Y	Y	
lzo	Y ⁶	Very fast	Medium	com.hadoop.compression.lzo.LzoCodec	Y	Y	LZO requires installation on every worker node
bzip2	Y	Slow	Very high	org.apache.hadoop.io.compress.BZip2Codec	Y	Y	Uses pure Java for splittable version
zlib	N	Slow	Medium	org.apache.hadoop.io.compress.DefaultCodec	Y	Y	Default compression codec for Hadoop
Snappy	N	Very Fast	Low	org.apache.hadoop.io.compress.SnappyCodec	N	Y	There is a pure Java port of Snappy but it is not yet available in Spark/Hadoop

Example of Spark Programming

Example 6-1. Sample call log entry in JSON, with some fields removed

```
{"address": "address here", "band": "40m", "callsign": "KK6JLK", "city": "SUNNYVALE",
"contactlat": "37.384733", "contactlong": "-122.032164",
"county": "Santa Clara", "dxcc": "291", "fullname": "MATTHEW McPherrin",
"id": 57779, "mode": "FM", "mylat": "37.751952821", "mylong": "-122.4208688735", ...}
```

Example 6-2. Accumulator empty line count in Python

```
file = sc.textFile(inputFile)
# Create Accumulator[Int] initialized to 0
blankLines = sc.accumulator(0)

def extractCallSigns(line):
    global blankLines    # Make the global variable accessible
    if (line == ""):
        blankLines += 1
    return line.split(" ")

callSigns = file.flatMap(extractCallSigns)
callSigns.saveAsTextFile(outputDir + "/callsigns")
print "Blank lines: %d" % blankLines.value
```

Numeric RDD Operations

Table 6-2. Summary statistics available from
StatsCounter

Method	Meaning
count()	Number of elements in the RDD
mean()	Average of the elements
sum()	Total
max()	Maximum value
min()	Minimum value
variance()	Variance of the elements
sampleVariance()	Variance of the elements, computed for a sample
stdev()	Standard deviation
sampleStdev()	Sample standard deviation

Removing outliers

Example 6-19. Removing outliers in Python

```
# Convert our RDD of strings to numeric data so we can compute stats and
# remove the outliers.
distanceNumerics = distances.map(lambda string: float(string))
stats = distanceNumerics.stats()
stddev = stats.stdev()
mean = stats.mean()
reasonableDistances = distanceNumerics.filter(
    lambda x: math.fabs(x - mean) < 3 * stddev)
print reasonableDistances.collect()
```

Machine Learning Library in Spark — MLlib

An example of using MLlib for text classification task, e.g., identifying spammy emails.

1. Start with an RDD of strings representing your messages.
2. Run one of MLlib's *feature extraction* algorithms to convert text into numerical features (suitable for learning algorithms); this will give back an RDD of vectors.
3. Call a classification algorithm (e.g., logistic regression) on the RDD of vectors; this will give back a model object that can be used to classify new points.
4. Evaluate the model on a test dataset using one of MLlib's evaluation functions.

Example: Spam Detection

Example 11-1. Spam classifier in Python

```
from pyspark.mllib.regression import LabeledPoint
from pyspark.mllib.feature import HashingTF
from pyspark.mllib.classification import LogisticRegressionWithSGD

spam = sc.textFile("spam.txt")
normal = sc.textfile("normal.txt")

# Create a HashingTF instance to map email text to vectors of 10,000 features.
tf = HashingTF(numFeatures = 10000)
# Each email is split into words, and each word is mapped to one feature.
spamFeatures = spam.map(lambda email: tf.transform(email.split(" ")))
normalFeatures = normal.map(lambda email: tf.transform(email.split(" ")))

# Create LabeledPoint datasets for positive (spam) and negative (normal) examples.

positiveExamples = spamFeatures.map(lambda features: LabeledPoint(1, features))
negativeExamples = normalFeatures.map(lambda features: LabeledPoint(0, features))
trainingData = positiveExamples.union(negativeExamples)
trainingData.cache() # Cache since Logistic Regression is an iterative algorithm.

# Run Logistic Regression using the SGD algorithm.
model = LogisticRegressionWithSGD.train(trainingData)

# Test on a positive example (spam) and a negative one (normal). We first apply
# the same HashingTF feature transformation to get vectors, then apply the model.
posTest = tf.transform("O M G GET cheap stuff by sending money to ...".split(" "))
negTest = tf.transform("Hi Dad, I started studying Spark the other ...".split(" "))
print "Prediction for positive test example: %g" % model.predict(posTest)
print "Prediction for negative test example: %g" % model.predict(negTest)
```

Term Frequency — Inverse Document Frequency (TF-IDF)

The value of word is reduced more if it is used frequently across all the documents in the dataset.

To calculate the inverse document frequency, the document frequency (DF) for each word is first calculated. Document frequency is the number of documents the word occurs in. The number of times a word occurs in a document isn't counted in document frequency. Then, the inverse document frequency or IDF_i for a word, w_i , is

$$IDF_i = \frac{1}{DF_i}$$

$$W_i = TF_i \cdot IDF_i = TF_i \cdot \frac{N}{DF_i} \quad \text{or} \quad W_i = TF_i \cdot \log \frac{N}{DF_i}$$

Item-based recommendation algorithm

Feature Extraction Example — TF-IDF

Example 11-7. Using HashingTF in Python

```
>>> from pyspark.mllib.feature import HashingTF

>>> sentence = "hello hello world"
>>> words = sentence.split() # Split sentence into a list of terms
>>> tf = HashingTF(10000) # Create vectors of size S = 10,000
>>> tf.transform(words)
SparseVector(10000, {3065: 1.0, 6861: 2.0})

>>> rdd = sc.wholeTextFiles("data").map(lambda (name, text): text.split())
>>> tfVectors = tf.transform(rdd) # Transforms an entire RDD
```

Example 11-8. Using TF-IDF in Python

```
from pyspark.mllib.feature import HashingTF, IDF

# Read a set of text files as TF vectors
rdd = sc.wholeTextFiles("data").map(lambda (name, text): text.split())
tf = HashingTF()
tfVectors = tf.transform(rdd).cache()

# Compute the IDF, then the TF-IDF vectors
idf = IDF()
idfModel = idf.fit(tfVectors)
tfIdfVectors = idfModel.transform(tfVectors)
```

Linear Regression

Example 11-10. Linear regression in Python

```
from pyspark.mllib.regression import LabeledPoint
from pyspark.mllib.regression import LinearRegressionWithSGD

points = # (create RDD of LabeledPoint)
model = LinearRegressionWithSGD.train(points, iterations=200, intercept=True)
print "weights: %s, intercept: %s" % (model.weights, model.intercept)
```

Classifiers

Logistic regression

Logistic regression is a binary classification method that identifies a linear separating plane between positive and negative examples. In MLlib, it takes `LabeledPoints` with label 0 or 1 and returns a `LogisticRegressionModel` that can predict new points.

Support Vector Machines

Support Vector Machines, or SVMs, are another binary classification method with linear separating planes, again expecting labels of 0 or 1. They are available through the `SVMWithSGD` class, with similar parameters to linear and logistic regression. The returned `SVMModel` uses a threshold for prediction like `LogisticRegressionModel`.

Naive Bayes

Naive Bayes is a multiclass classification algorithm that scores how well each point belongs in each class based on a linear function of the features. It is commonly used in text classification with TF-IDF features, among other applications. MLlib implements Multinomial Naive Bayes, which expects nonnegative frequencies (e.g., word frequencies) as input features.

Logistic regression

Logistic regression describes a kind of classification model in which the predictor variables are combined with linear weights and then passed through a soft-limit function that limits the output to the range from 0 to 1. Logistic regression is closely related to other models such as a perceptron (where the soft limit is replaced by a hard limit), neural networks (where multiple layers of linear combination and soft limiting are used) and naive Bayes (where the linear weights are determined strictly by feature frequencies assuming independence). Logistic regression can't separate all possible classes, but in very high dimensional problems or where you can introduce new variables by combining other predictors, this is much less of a problem. The mathematical simplicity of logistic regression allows very efficient and effective learning algorithms to be derived.

Stochastic Gradient Descent (SGD)

Both **statistical estimation** and **machine learning** consider the problem of minimizing an **objective function** that has the form of a sum:

$$Q(w) = \sum_{i=1}^n Q_i(w),$$

where the **parameter** w is to be **estimated** and where typically each summand function $Q_i()$ is associated with the i -th **observation** in the **data set** (used for training).

- Choose an initial vector of parameters w and learning rate α .
- Randomly shuffle examples in the training set.
- Repeat until an approximate minimum is obtained:
 - For $i = 1, 2, \dots, n$, do:
 - $w := w - \alpha \nabla Q_i(w)$.

Let's suppose we want to fit a straight line $y = w_1 + w_2x$ to a training set of two-dimensional points $(x_1, y_1), \dots, (x_n, y_n)$ using **least squares**. The objective function to be minimized is:

$$Q(w) = \sum_{i=1}^n Q_i(w) = \sum_{i=1}^n (w_1 + w_2x_i - y_i)^2.$$

The last line in the above pseudocode for this specific problem will become:

$$\begin{bmatrix} w_1 \\ w_2 \end{bmatrix} := \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} - \alpha \left[\begin{array}{c} \sum_{i=1}^n 2(w_1 + w_2x_i - y_i) \\ \sum_{i=1}^n 2x_i(w_1 + w_2x_i - y_i) \end{array} \right].$$

Support Vector Machine (SVM)

maximize boundary distances; remembering “support vectors”

nonlinear kernels

Training set:

sex	height (feet)	weight (lbs)	foot size(inches)
male	6	180	12
male	5.92 (5'11")	190	11
male	5.58 (5'7")	170	12
male	5.92 (5'11")	165	10
female	5	100	6
female	5.5 (5'6")	150	8
female	5.42 (5'5")	130	7
female	5.75 (5'9")	150	9

Classifier using Gaussian distribution assumptions:

sex	mean (height)	variance (height)	mean (weight)	variance (weight)	mean (foot size)	variance (foot size)
male	5.855	3.5033e-02	176.25	1.2292e+02	11.25	9.1667e-01
female	5.4175	9.7225e-02	132.5	5.5833e+02	7.5	1.6667e+00

Test Set:

$$\text{posterior(male)} = \frac{P(\text{male}) p(\text{height}|\text{male}) p(\text{weight}|\text{male}) p(\text{footsize}|\text{male})}{\text{evidence}}$$

sex	height (feet)	weight (lbs)	foot size(inches)
sample	6	130	8

$$\text{evidence} = P(\text{male}) p(\text{height}|\text{male}) p(\text{weight}|\text{male}) p(\text{footsize}|\text{male}) + P(\text{female}) p(\text{height}|\text{female}) p(\text{weight}|\text{female}) p(\text{footsize}|\text{female})$$

$$P(\text{male}) = 0.5$$

$$p(\text{height}|\text{male}) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(\frac{-(6-\mu)^2}{2\sigma^2}\right) \approx 1.5789.$$

$$p(\text{weight}|\text{male}) = 5.9881 \cdot 10^{-6}$$

$$p(\text{foot size}|\text{male}) = 1.3112 \cdot 10^{-3}$$

$$\text{posterior numerator (male)} = \text{their product} = 6.1984 \cdot 10^{-9}$$

$$P(\text{female}) = 0.5$$

$$p(\text{height}|\text{female}) = 2.2346 \cdot 10^{-1}$$

$$p(\text{weight}|\text{female}) = 1.6789 \cdot 10^{-2}$$

$$p(\text{foot size}|\text{female}) = 2.8669 \cdot 10^{-1}$$

$$\text{posterior numerator (female)} = \text{their product} = 5.3778 \cdot 10^{-4}$$

==> female

Decision trees and Random Forests

Figure 11-2. An example decision tree predicting whether a user might buy a product

In MLlib, you can train trees using the `mllib.tree.DecisionTree` class, through the static methods `trainClassifier()` and `trainRegressor()`.

Random forests are an **ensemble learning** method for **classification** (and **regression**) that operate by constructing a multitude of **decision trees** at training time and outputting the class that is the **mode** of the classes output by individual trees.

The training algorithm for random forests applies the general technique of **bootstrap aggregating**, or bagging, to tree learners. Given a training set $X = x_1, \dots, x_n$ with responses $Y = y_1$ through y_n , bagging repeatedly selects a **bootstrap sample** of the training set and fits trees to these samples:

For $b = 1$ through B :

1. Sample, with replacement, n training examples from X, Y ; call these X_b, Y_b .
2. Train a decision or regression tree f_b on X_b, Y_b .

After training, predictions for unseen samples x' can be made by averaging the predictions from all the individual regression trees on x' :

$$\hat{f} = \frac{1}{B} \sum_{b=1}^B \hat{f}_b(x')$$

or by taking the majority vote in the case of decision trees.

Random forest uses a modified tree learning algorithm that selects, at each candidate split in learning process, a random subset of the features.

Clustering example

Steps on clustering

K-mean clustering

K-means clustering in action. Starting with three random points as centroids (top left), the map stage (top right) assigns each point to the cluster nearest to it. In the reduce stage (bottom left), the associated points are averaged out to produce the new location of the centroid, leaving you with the final configuration (bottom right). After each iteration, the final configuration is fed back into the same loop until the centroids come to rest at their final positions.

Clustering

K-means

MLlib includes the popular K-means algorithm for clustering, as well as a variant called K-means|| that provides better initialization in parallel environments.⁵ K-means|| is similar to the K-means++ initialization procedure often used in single-node settings.

`initializationMode`

The method to initialize cluster centers, which can be either “k-means||” or “random”; k-means|| (the default) generally leads to better results but is slightly more expensive.

`maxIterations`

Maximum number of iterations to run (default: 100).

`runs`

Number of concurrent runs of the algorithm to execute. MLlib’s K-means supports running from multiple starting positions concurrently and picking the best result, which is a good way to get a better overall model (as K-means runs can stop in local minima).

Like other algorithms, you invoke K-means by creating a `mllib.clustering.KMeans` object (in Java/Scala) or calling `KMeans.train` (in Python).

Collaborative Filtering

Collaborative Filtering and Recommendation

Collaborative filtering is a technique for recommender systems wherein users' ratings and interactions with various products are used to recommend new ones. Collaborative filtering is attractive because it only needs to take in a list of user/product interactions: either "explicit" interactions (i.e., ratings on a shopping site) or "implicit" ones (e.g., a user browsed a product page but did not rate the product).

Alternating Least Squares

MLlib includes an implementation of Alternating Least Squares (ALS), a popular algorithm for collaborative filtering that scales well on clusters.⁶ It is located in the `mllib.recommendation.ALS` class.

Collaborative Filtering (CF)

Leveraging opinions of like-minded users

Given

Dimensionality Reduction

Principal component analysis

Given a dataset of points in a high-dimensional space, we are often interested in reducing the dimensionality of the points so that they can be analyzed with simpler tools. For example, we might want to plot the points in two dimensions, or just reduce the number of features to train models more effectively.

Singular value decomposition

MLlib also provides the lower-level singular value decomposition (SVD) primitive. The SVD factorizes an $m \times n$ matrix A into three matrices $A \approx U\Sigma V^T$, where:

- U is an orthonormal matrix, whose columns are called left singular vectors.
- Σ is a diagonal matrix with nonnegative diagonals in descending order, whose diagonals are called singular values.
- V is an orthonormal matrix, whose columns are called right singular vectors.

应用场景

Hadoop – 极大数据量 > TB - PB 级

- 单次海量数据的离线分析处理
- 大规模 Web 信息搜索
- 数据密集型并行计算

Spark – 内存可容纳 \approx TB 级

- 多次操作特定数据集, 迭代运算
- 搜索引擎 – PageRank
- 计算相似 – Single Source Shortest Path (单源最短路径)

性能

- Hadoop : 适合不能全部读入内存；单次读取、类似 ETL （抽取、转换、加载）操作的任务，比如**数据转化、数据整合**等时
- Spark : 适合数据不太大内存放得下，重复读取同样数据**迭代计算**

上手

- Hadoop : **Java编写**，需要学习语法，有一些工具（Pig、Hive等）简化
- Spark : **Scala、Java和Python**，还支持交互式命令模式

兼容性

- Spark**兼容**Hadoop数据源

容错

- Hadoop : 硬盘静态数据, 硬盘驱动失败处**自动重启**执行
- Spark : 内存失效, 需要**手动设置**checkpoint

数据处理

- Hadoop : **批处理**
- Spark : **实时**/批数据处理, **迭代任务**
